(54) Title: N-FORMYL HYDROXYLAMINE COMPOUNDS AS INHIBITORS OF PDF

(57) Abstract: n-[01-oxo-2-alkyl-3-(N-hydroxyformamido)-propyl]-(carbonylamino-aryl or heteroaryl)- azacyclo $_{4-7}$ alkanes or thiazacyclo $_{4-7}$ alkanes or imidazacyclo $_{4-7}$ alkanes have interesting properties, e.g. in the treatment or prevention of disorders amenable to treatment by peptidyl deformylase inhibitors such as treatment of bacterial infections.

N-FORMYL HYDROXYLAMINE COMPOUNDS AS INHIBITORS OF PDF

This invention is directed to novel N-formyl hydroxylamine compounds, to the uses of these compounds in various medicinal applications, including treating disorders amenable to treatment by peptidyl deformylase inhibitors such as treatment of bacterial infections, and to pharmaceutical compositions comprising these compounds.

Treatment of microbial infection in host organisms requires an effective means to kill the microbe while doing as little harm to the host as possible. Accordingly, agents which target characteristics unique to a pathology-causing microorganism are desirable for treatment. Penicillin is an extremely well known example of such an agent. Penicillin acts by inhibiting biosynthesis of bacterial cell walls. Since mammalian cells do not require cell walls for survival, administration of penicillin to a human infected with bacteria may kill the bacteria without killing human cells.

However, the use of antibiotics and antimicrobials has also resulted in increased resistance to these agents. As bacteria become resistant to older, more widely used antimicrobial agents, new antimicrobials must be developed in order to provide effective treatments for human and non-human animals suffering from microbial infection.

Peptide deformylase is a metallopeptidase found in prokaryotic organisms such as bacteria. Protein synthesis in prokaryotic organisms begins with N-formyl methionine (fMet). After initiation of protein synthesis, the formyl group is removed by the enzyme peptide deformylase (PDF); this activity is essential for maturation of proteins. It has been shown that PDF is required for bacterial growth (Chang et al., J. Bacteriol., Vol. 171, pp. 4071-4072 (1989); Meinnel et al., J. Bacteriol., Vol. 176, No. 23, pp. 7387-7390 (1994); Mazel et al., EMBO J., Vol. 13, No. 4, pp. 914-23 (1994)). Since protein synthesis in eukaryotic organisms does not depend on fMet for initiation, agents that will inhibit PDF are attractive candidates for development of new antimicrobial and antibacterial drugs. Prokaryotic organisms, including disease-causing prokaryotes, are described in Balows A, Truper HG, Dworkin M, Harder W and Schleifer K-H (eds.), "The Prokaryotes", 2nd ed., New York: Springer-Verlag (1992); and Holt JG (editor-in-chief), "Bergey's Manual of Systematic Bacteriology", Vols. 1-4, Baltimore: Williams & Wilkins (1982, 1986, 1989).

PDF is part of the metalloproteinase superfamily. While PDF clearly shares many of the features which characterize metalloproteinases, it differs from other members of the

superfamily in several important respects. First, the metal ion in the active enzyme appears to be Fe (II), or possibly another divalent cationic metal, instead of the zinc ion more commonly encountered (Rajagopalan et al., J. Am. Chem. Soc., Vol. 119, pp. 12418-12419 (1997)). Second, the divalent ion appears to play an important role, not only in catalysis, but also in the structural integrity of the protein. Third, the third ligand of the divalent ion is a cysteine, rather than a histidine or a glutamate, as in other metalloproteinases and is not located at the C-terminal side of the HEXXH motif but far away along the amino acid sequence and N-terminal to the motif. Finally, the solution structure shows significant differences in the secondary and tertiary structure of PDF compared to other prototypical metalloproteinases (see Meinnel et al., J. Mol. Biol., Vol. 262, pp. 375-386 (1996)). PDF from *E. coli*, *Bacillus stearothermophilus*, and *Thermus thermophilus* have been characterized (see Meinnel et al., J. Mol. Biol., Vol. 267, pp. 749-761 (1997)). The enzyme studied by Meinnel et al. contained a zinc ion as the divalent ion and the structural features summarized above were obtained from zinc-containing proteins. The structure of the protein has also been determined by NMR (see O'Connell et al., J. Biomol. NMR, Vol. 13, No. 4, pp. 311-324 (1999)).

Metalloproteinases are critical to many aspects of normal metabolism. The class known as matrix metalloproteinases (MMPs) are involved in tissue remodeling, such as degradation of the extracellular matrix. These enzymes are believed to play a role in normal or beneficial biological events such as the formation of the corpus luteum during pregnancy (see Liu et al., Endocrinology, Vol. 140, No. 11, pp. 5330-5338 (1999)), wound healing (Yamagiwa et al., Bone, Vol. 25, No. 2, pp. 197-203 (1999)), and bone growth in healthy children (Bord et al., Bone, Vol. 23, No. 1, pp. 7-12 (1998)). Disorders involving metalloproteinases have been implicated in several diseases such as cancer, arthritis, and autoimmune diseases.

Because of the importance of MMPs in normal physiological processes, it would be preferable to develop agents that inhibit PDF, a metalloproteinase present only in prokaryotes, while avoiding significant inhibition of MMPs. Alternatively, PDF inhibitors which also inhibit MMPs may be of use where the therapeutic benefits of inhibiting PDF outweigh the risk of side effects from MMP inhibition.

A wide variety of compounds have been developed as candidate inhibitors of MMPs and other metalloproteinases, and much effort has also been directed at synthetic methods for these compounds and related compounds (see Izquierdo-Martin et al., J. Am. Chem. Soc., Vol. 114, pp. 325-331 (1992); Cushman et al., Chapter 5, "Specific Inhibitors of Zinc

Metallopeptidases", Topics in Molecular Pharmacology, Burgen & Roberts, eds. (1981); Mohler et al., Nature, Vol. 370, pp. 218-220 (1994); Gearing et al., Nature, Vol. 370, pp. 555-557 (1994); McGeehan et al., Nature, Vol. 370, pp. 558-561 (1994); U.S. Patent Nos. 4,052,511, 4,303,662, 4,311,705, 4,321,383, 4,599,361, 4,804,676, 5,128,346, 5,256,657, 5,268,384, 5,447,929, 5,453,423, 5,552,419, 5,614,625, 5,643,908, 5,712,300, and 5,869,518; European patent publications EP 236872, EP 274453, EP 334244, EP 423943, EP 489577, EP 489579, EP 497192, EP 574758; and International PCT Patent Applications Publication Nos. Research on inhibitors of PDF is much less extensive than that for inhibitors of MMPs. N-formyl hydroxylamine derivatives are described in International Patent Application WO 99/39704. Peptide aldehyde inhibitors of PDFs are described in Durand et al., Arch. Biochem. Biophys., Vol. 367, No. 2, pp. 297-302 (1999). The PDF inhibitor (S)-2-O-(H-phosphonoxy)-L-caproyl-L-leucyl-p-nitroanilide is described in Hao et al., Biochemistry, Vol. 38, pp. 4712-4719 (1999), and peptidyl H-phosphonate inhibitors of PDF are discussed in Hu et al., Bioorg. Med. Chem. Lett., Vol. 8, pp. 2479-2482 (1998). Formylated peptides and pseudopeptides are described in Meinnel et al., Biochemistry, Vol. 38, No. 14, pp. 4288-4295 (1999) as inhibitors of PDF.

In view of the importance of identifying new antibiotics to treat bacteria resistant to existing antibiotics, it is desirable to develop novel inhibitors of PDF for evaluation and use as antibacterial and antimicrobial agents. The present invention fulfills this need.

The solution is heated to 80°C during which time a precipitate appears, and then gradually re-dissolves over 1 h. The reaction mixture is stirred at 80°C overnight then cooled to rt. The solvents are removed under reduced pressure, and the residue is dissolved in EtOAc, washed successively with 1M HCl and brine, dried over anhydrous Na_2SO_4, and filtered. The filtrate is concentrated to give the title compound **A-2** as a clear oil.

Step 2: 4-benzyl-3-(2-butyl-acryloyl)-oxazolidin-2-one (A-3)

2-*n*-Butyl acrylic acid (9.90 g, 77.2 mmol, and 1 equiv.) is dissolved in dry THF (260 ml) and cooled to -78°C under nitrogen. Hunig's base (17.5 ml, 100.4 mmol, 1.3 equiv.) and pivaloyl chloride (9.5 ml, 77.2 mmol, 1 equiv.) are added at such a rate that the temperature remains below -60°C. The mixture is stirred at -78°C for 30 min, warmed to rt for 2 h, and finally

cooled back to -78°C. In a separate flask, (*S*)-(-)-4-benzyl-2-oxazolidinone (13.49 g, 77.24 mmol) is dissolved in dry THF (150 ml) and cooled to -78°C under nitrogen. *n*-Butyllithium (2.5M solution in hexanes, 30.9 ml, 77.2 mmol, 1 equiv.) is added slowly at -78°C, and the mixture is stirred for 30 min at rt. The resulting anion is slowly transferred via a cannula into the original reaction vessel. The mixture is allowed to warm to rt and is stirred overnight at rt. The reaction is quenched with 1M $KHCO_3$, and the solvents are removed under reduced pressure. The residue is partitioned between EtOAc and water. The organic layer is washed with brine, dried over anhydrous Na_2SO_4, filtered, and concentrated to give a yellow oil which is purified by FC (hexane:EtOAc = 4:1) to yield the title compound **A-3** as a white solid.

The compounds of the invention, e.g. the compounds of formula (I), in free form or in pharmaceutically acceptable salt from or a prodrug thereof, exhibit valuable pharmacological properties, e.g. as anti-infectious agents, e.g. as indicated in *in vitro* and *in vivo* tests and are therefore indicated for therapy.

A. Inhibition of Peptide Deformylase Activity

The PDF/FDH coupled assay (Lazennec et al., Anal. Biochem., Vol. 224, pp. 180-182 (1997)) is used. In this coupled assay, the formate released by PDF from its substrate fMAS is oxidized by the coupling enzyme FDH, reducing one molecule of NAD^+ to NADH, which causes an increase in absorption at 340 nM. All assays are carried out at rt in a buffer of 50 mM HEPES, pH 7.2, 10 mM NaCl, 0.2 mg/ml BSA, in half-area 96-well microtiter plates (Corning). The reaction is initiated by adding a mixture of 0.5 Unit/ml FDH, 1 mM NAD^+, and fMAS at the desired concentration. To determine IC_{50} (the concentration needed to inhibit 50% of enzyme activity) values, PDF is pre-incubated for 10 minutes with varying concentrations of the inhibitor, and the deformylation reaction is initiated by the addition of reaction mixture containing 4 mM fMAS. The initial reaction velocity, y, is measured as the initial rate of absorption increase at 340 nM using a SpectraMax plate reader (Molecular Devices, Sunnyvale, CA). The inhibitor concentration [In] at which 50% of the enzyme activity is inhibited, IC_{50}, is calculated using the following formula:

$$y = y_o/(1 + [In]/IC_{50})$$

where y_o is the reaction velocity in the absence of inhibitor. Solving this equation for IC_{50} at the [In] when $y = y_o/2$ yields IC_{50}. The IC_{50} is calculated based on a nonlinear least-square regression fit using a commercial software package (Deltapoint, Inc., Chicago, IL.).

Using this assay, the IC_{50} of various compounds of the invention is determined. The IC_{50} for the various compounds is determined against deformylase enzyme containing nickel and zinc as the metal ion. The IC_{50} values of preferred compounds of formula (I) determined for the zinc-containing deformylase range from about 0.001 µM to about 0.2 µM. The IC_{50} values of preferred compounds of formula (I) determined for the nickel-containing deformylase ranged from about 0.005 µM to about 3 µM.

B. Assay for Testing Antimicrobial Activity

Minimum inhibitory concentrations (MICs) are determined using the microdilution method in 96-well format plates. Compounds are suspended in DMSO at 5 or 10 mg/ml and stored at 4°C until used. They are diluted in Mueller-Hinton Broth (MHB) or Trypticase Soy Broth (TSB) and used for MIC determination. The range of concentrations tested is 64-0.0625 µg/ml final concentration using a two-fold dilution system.

The inoculum is prepared from cells grown on Trypticase Soy Agar (TSA) and incubated overnight at 35°C, 5-10 colonies are used to inoculate MHB or TSB broths, and the culture is incubated overnight at 35°C. The overnight culture is diluted 1:10, incubated for 1 hour at 35°C, diluted to the appropriate inoculum size and applied to the wells containing broth and test compound. Inoculum sizes are 2×10^4 CFU/ml.

Plates are incubated at 35°C for 48 hours and MIC are recorded after 18 hours of incubation for bacteria. MIC is defined as the lowest concentration of a compound of the invention that does not produce visible growth after incubation.

Minimum inhibitory concentration for various preferred compounds of formula (I) ranges from about 0.25 µg/ml to about 32 µg/ml against *H.* influenza (four strains), from about 0.001 µg/ml to greater than 8 µg/ml against *S. aureus* (four strains), from about 0.016 µg/ml to about 16 µg/ml against *S. pneumonia* (four strains), and from about 0.008 µg/ml to about 16 µg/ml against *M. catarrhalis*. The deformylase enzyme is obtained from *E. coli*.

C. Demonstration of Selective Inhibition of PDF Compared to MMP-7 (Matrilysin)

As noted previously, inhibitors which are selective for peptidyl deformylase over MMPs are desirable in order to avoid side effects.

In order to test the compounds of the invention for possible inhibitory effects on MMPs, the following assay for MMP-7 (matrilysin) is used.

MMP-7 (Matrilysin) Assay:

Matrilysin activity is assayed using a thio-peptide (Pro-Leu-Gly-S-Leu-Leu-Gly) as substrate. Upon enzyme hydrolysis, the thiolate is released as a product. The thiolate thus generated reacts with DTNB (dithionitrobenzene), giving rise to a yellow color which is monitored at 405 nM. The assay is carried out at rt; the assay buffer contains 50 mM Tricine, pH 7.5, 0.2 M NaCl, 10 mM $CaCl_2$, and 0.05% Brij, in a half-area 96-well microtiter plate. The reaction is initiated by adding a mixture of 200 TM DTNB and 100 TM thiopeptide in buffer. To determine IC_{50} (the concentration needed to inhibit 50% of enzyme activity) values, MMP-7 is preincubated for 10 minutes with varying concentrations of compounds of the invention, and the hydrolysis initiated by the addition of reaction mixture containing thiopeptide and DTNB. The reaction rate is recorded as the absorbance increase in OD_{405} over 30 minutes

using a SpectraMax plate reader (Molecular Devices, Sunnyvale, CA). The inhibitor concentration [In] at which 50% of the enzyme activity is inhibited, IC_{50}, is calculated using the following formula:

$$y = y_o/(1 + [In]/IC_{50})$$

where y_o is the reaction velocity in the absence of inhibitor. Solving this equation for IC_{50} at the [In] when $y = y_o/2$ yields IC_{50}.

Using this assay, the IC_{50} of various compounds of the invention are determined. The IC_{50} of various preferred compounds of formula (I) against MMP-7 ranges from greater than 10 μM to greater than 100 μM, whereas the IC_{50} of these same compounds against zinc-containing PDF ranges from about 0.005 μM to about 5 μM, and against nickel-containing PDF ranged from about 0.001 μM to about 0.3 μM. Accordingly, compounds of the invention have superior selectivity for PDF as compared to their activity against MMP-7. Similar selectivity of the compounds for peptidyl deformylase over MMP-1, MMP-2, MMP-3, MMP-9, MMP-13, MT-MMP-1, and tissue necrosis factor converting enzyme is observed. Similar selectivity is also observed over other metalloproteinases such as angiotensin converting enzyme.

D. Mouse Septicemia Model for Determining *In Vivo* Efficacy

CD1 female out-bred mice (Charles River Laboratories) weighing 18-22 g each are injected intraperitoneally with 0.5 ml of a suspension containing 5×10^7 cfu of *S. aureus* (Smith strain) in 7% hog gastric mucosa (mucin). The mice are treated, either subcutaneously (s.c.), intravenously (i.v.) or orally (p.o.), 1 hour and 5 hours after infection. Six groups of six mice each are given different dosage levels representing two-fold dilutions of each compound to be tested (range of 100-0.1 mg/kg). Vancomycin is used as the control antibiotic and is administered s.c. Compounds of the invention are formulated in PBS and untreated controls are dosed with vehicle alone.

Deaths in each group are monitored daily for 6 days and cumulative mortality is used to determine the 50% protective doses (PD_{50}), which are calculated using the method of Reed and Muench. The PD_{50} (s.c.) in mice against *S. aureus* for several preferred compound of formula (I) ranges from about 0.1 mg/kg to greater than 12 mg/kg. The PD_{50} (p.o.) in mice against *S. aureus* for these same compounds of formula (I) ranges from 1 mg/ml to greater than 12 mg/kg.

E. Pharmacokinetics Study of PDF Inhibitors in Mice

The pharmacokinetics of PDF compounds are determined in CD1 female out-bred mice (Charles River Laboratories) weighing 20-25 g. PDF compounds are formulated in 20% cyclodextrin (Aldrich) and filtered through 0.22 µm filter for sterilization. Either single compound or mixtures of 4-6 compounds as a cassette are administered i.v. and p.o. at 10 ml/kg. The dose ranged from 3-15 mg/kg for each compound. At 0.083, 0.25, 0.5, 1, 2, 4 and 7 hours after dosing, serum samples are collected via cardiac puncture under anesthesia. Groups of four mice are used for each time point. The serum samples are stored at -80°C until analysis.

The serum protein is precipitated by addition of acetonitrile. The samples after protein precipitation are analyzed by LC/MS/MS method. Standard curve is obtained for each compound and used for determination of compound concentration in serum. The pharmacokinetics parameters including T_{max} (time of maximum concentration), C_{max} (maximum concentration), $t_{1/2}$ (terminal half-life), and AUC (area under the curve), are calculated according to standard method. The oral bioavailability is calculated as the ratio of AUC of p.o. administration vs. the AUC administered i.v. The preferred compounds of formula (I) exhibit oral bioavailability greater than 70%.

acceptable wetting agents, such as sodium lauryl sulphate. The tablets may be coated according to methods well-known in standard pharmaceutical practice.

Oral liquid preparations may be in the form of, for example, aqueous or oily suspensions, solutions, emulsions, syrups or elixirs, or may be presented as a dry product for reconstitution with water or another suitable vehicle before use. Such liquid preparations may contain conventional additives, such as suspending agents, for example, sorbitol, methyl cellulose, glucose syrup, gelatin, hydroxyethyl cellulose, carboxymethyl cellulose, aluminium stearate gel or hydrogenated edible fats; emulsifying agents, for example, lecithin, sorbitan monooleate, or acacia; non-aqueous vehicles (which may include edible oils), for example, almond oil, oily esters such as glycerine, propylene glycol, or ethyl alcohol; preservatives, for example, methyl or propyl p-hydroxybenzoate or sorbic acid, and, if desired, conventional flavoring or coloring agents.

For parenteral administration, fluid unit dosage forms are prepared utilizing the compound and a sterile vehicle, water being preferred. The compound, depending on the vehicle and concentration used, may be either suspended or dissolved in the vehicle or other suitable solvent. In preparing solutions, the compound may be dissolved in water for injection and filter sterilized before filling into a suitable vial or ampule and sealing. Advantageously, agents such as a local anesthetic preservative and buffering agents may be dissolved in the vehicle. To enhance the stability, the composition may be frozen after filling into the vial and the water removed under vacuum. The dry lyophilized powder is then sealed in the vial and an accompanying vial of water for injection may be supplied to reconstitute the liquid prior to use. Parenteral suspensions are prepared in substantially the same manner except that the compound is suspended in the vehicle instead of being dissolved and sterilization cannot be accomplished by filtration. The compound may be sterilized by exposure to ethylene oxide before suspending in the sterile vehicle. Advantageously, a surfactant or wetting agent is included in the composition to facilitate uniform distribution of the compound.

The compounds of the invention, e.g. the compounds of formula (I), may be administered in free form or in pharmaceutically acceptable salt form e.g. as indicated above. Such salts may be prepared in conventional manner and exhibit the same order of activity as the free compounds.

"Treating" or "treatment" of a disease includes:

(1) preventing the disease, i.e. causing the clinical symptoms of the disease not to develop in a subject, e.g. a mammal, that may be exposed to or predisposed to the disease but does not yet experience or display symptoms of the disease,

An "effective peptidyl deformylase inhibiting amount" means the amount of a compound, a pharmaceutically acceptable salt thereof or a prodrug thereof, that when administered to a subject for treating an infectious disorder responsive to inhibition of peptidyl deformylase or for inhibiting peptidyl deformylase, is sufficient to inhibit peptidyl deformylase. The "effective peptidyl deformylase inhibiting amount" will vary depending on the compound, salt thereof or prodrug thereof, employed, the microorganism that is inhibited in the subject, the age,

weight, sex, medical condition, species, disorder and its severity, of the subject to be treated, and the route of administration, but may nevertheless be readily determined by one skilled in the art.

6. A therapeutic combination, e.g. a kit, comprising a) a compound of the invention, e.g. of formula (I), a pharmaceutically acceptable salt thereof or a prodrug thereof, and b) at least one second therapeutic agent. Component a) and component b) may be used concomitantly or in sequence. The kit may comprise instructions for its administration.

The present invention is not limited to the clinical use of the compounds of the invention, i.e, in the treatment of infection in a subject. The compounds of the invention are useful to inhibit bacteria wherever it is desired to inhibit bacteria by contacting the bacteria with one or more compounds of the invention. Because of their ability to inhibit bacteria, the compounds of the invention are particularly useful to prevent contamination of cell cultures. As used in this context, the term "inhibit" means the suppression, control, stasis, or kill of bacteria. Eukaryotic cells, in particular animal cells, are often cultured for various reasons such as for their ability to produce substances such as proteins. Examples of such cells include Chinese hamster ovary cells (CHO cells), African green monkey kidney cells, hybridomoas constructed by fusing a parent cell (myeloma, etc.) with a useful substance-producing normal cell (lymphocyte, etc.), and the like. Typically, the compounds of the invention are incorporated into cell culture media at a bacteria inhibiting amount, e.g., a concentration of about 0.0001 to about 10 microgram/ml, preferably about 0.0001 to about 1 microgram/ml, and more preferably about 0.001 to about 0.1 microgram/ml. Any conventional cell culture medium known in the art can be used.

In accordance with the foregoing the present invention provides in a yet further aspect:

7. A method for preventing bacterial contamination of a cell culture medium comprising incorporating into said cell culture medium a bacteria inhibiting amount of a compound of the invention, e.g. of formula (I), or a pharmaceutically acceptable salt thereof.
8. A cell culture medium comprising. a bacteria inhibiting amount of a compound of the invention, e.g. of formula (I), or a pharmaceutically acceptable salt thereof.

The foregoing invention has been described in some detail by way of illustration and example. It will be obvious to one of skill in the art that changes and modifications may be practiced within the scope of the appended claims. All patents, patent applications and publications cited in this application are hereby incorporated by reference in their entirety.
